

Core Systems Startup Plan

This document outlines the general start up process for the core systems sub-team, specifically the systems that need to be in place to allow other teams to start development.

Dependencies

- SQLite for database?
 - o I can teach others how to install, shouldn't be too complicated

General Core Systems

Identity Management

- Handles the user sessions, requires username, userID, password?

Game Registry

- System that stores which games are available to play and information about them, GameID, Title, Thumbnail, Description, Launch Command

Competition System

- System that the game reports scores etc back to the main system for ranking.

Persistence System / Data Management

- Stores data in JSON or similar file format to act as a stub database
- Or can store in .db file (SQL), since planning on implementing an actual database anyway

Work for Client / UI Team

- UI for login / signup
 - o Need username and password input fields
 - Password Requirements?
 - "Forgot Password" function?
 - o Need ability to switch screens/popups/display from login screen to lobby/home
 - o Need an ability to create new accounts

- If using JavaFX or something similar, set up Controller class to pass username and password into a stub function on login
 - Actual function will be taken care of by platform core
 - If not planning on using JavaFX, just make sure username and password is somehow passed to function
- UI for lobby / home where games are listed.
- UI for game view / information before starting (think how Netflix has movie information screen that you can pop up before starting a movie)
- Global leaderboard dashboard
 - Maybe include this as a tab or something inside lobby/home?
- Admin console (since server is stubbed, we will need it to simulate server responses)

Formatted: Indent: Left: 0.75"

Work for Quality and Testing

Begin planning for how to test the general program flow of:

Registers -> Logs in -> User Selects Game -> User Scores 100 -> Leaderboard updates

Rules and Validation

- Develop rules for score submission, when the competition system passes data back to the main system, each game should have a validation check to ensure no hacked or glitched scores. This will need to be done for each game. Implement into competition system once logic is completed.
- More information on the data types that will be sent for verification will come later. But likely and integer score, a userID integer, and a gameId or title integer or string

Integration and Release

- Define rules for how you will communicate with the other sub teams on merging branches etc. Someone needs to be available to peer review code when merges occur so we don't get stuck.
- We need to define a versioning system for every time a new branch is merged, for example v0.0.1, v0.0.2
